Comparison of ranibizumab and bevacizumab for neovascular age-related macular degeneration (AMD) according to LUCAS treat-and-extend protocol

Berg K, Pedersen T R, Sandvik L, et al. *Ophthalmology.* 2014:1-7 doi: http://dx.doi.org/10.1016/j.ophtha.2014.07.041

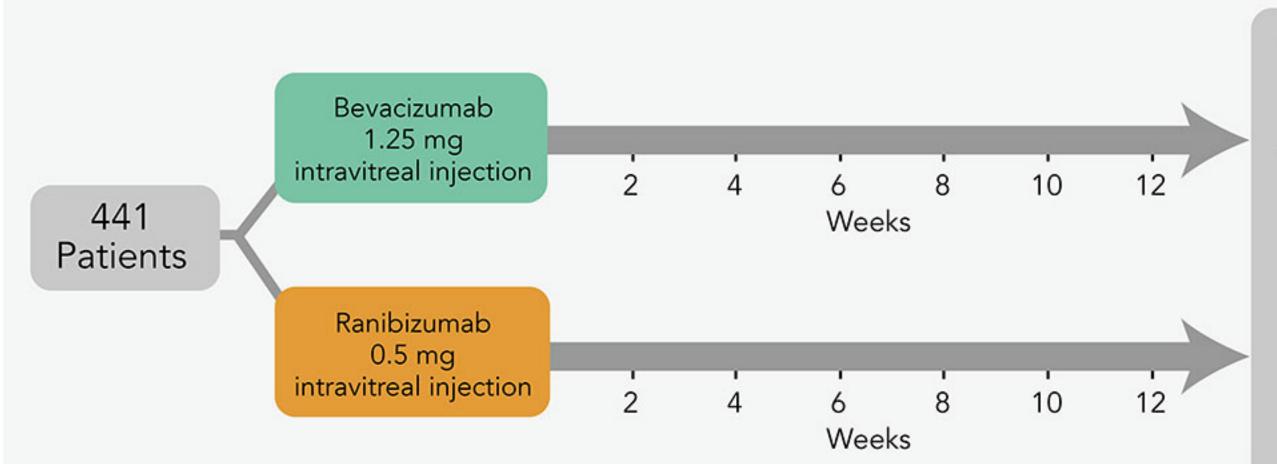

The objective of this trial was to compare the efficacy and safety of bevacizumab versus ranibizumab when administered according to a treat-and-extend protocol for the treatment of neovascular AMD.

This was a multicenter, randomized, noninferiority trial with a noninferiority limit of 5 letters

Monthly injections were given until inactive disease was achieved. The patients were then followed with a gradual extension of treatment interval by 2 weeks at a time up to a maximum of 12 weeks.

The patients were examined and injected every 4 weeks until no signs of active AMD were found, as determined by optical coherence tomography (OCT) and biomicroscopic fundus examinations.

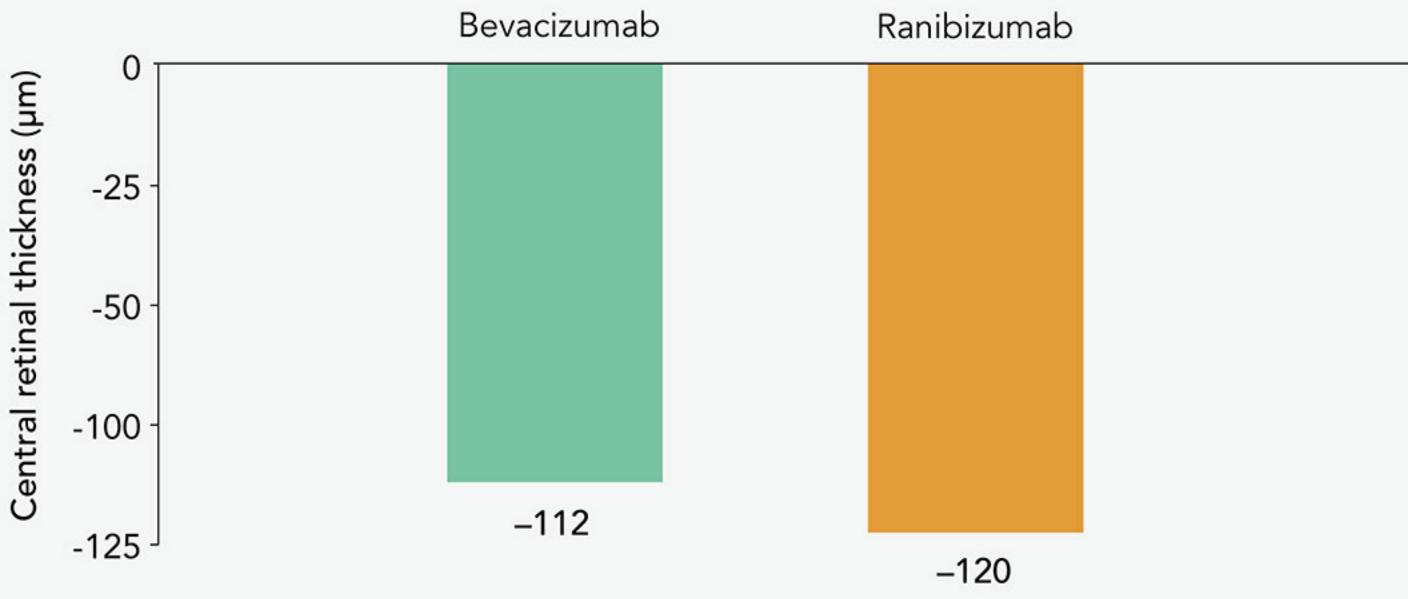

The primary outcome was the change in BCVA at 1 year as measured on the ETDRS visual acuity chart. Secondary outcomes included the number of injections, change in CRT as measured with OCT, and change of lesion size as measured on FA. The safety outcome was the occurrence of arteriothrombotic events.

BCVA = best corrected visual acuity; CRT = central retinal thickness; ETDRS = Early Treatment Diabetic Retinopathy Study; FA = fluorescein angiography.

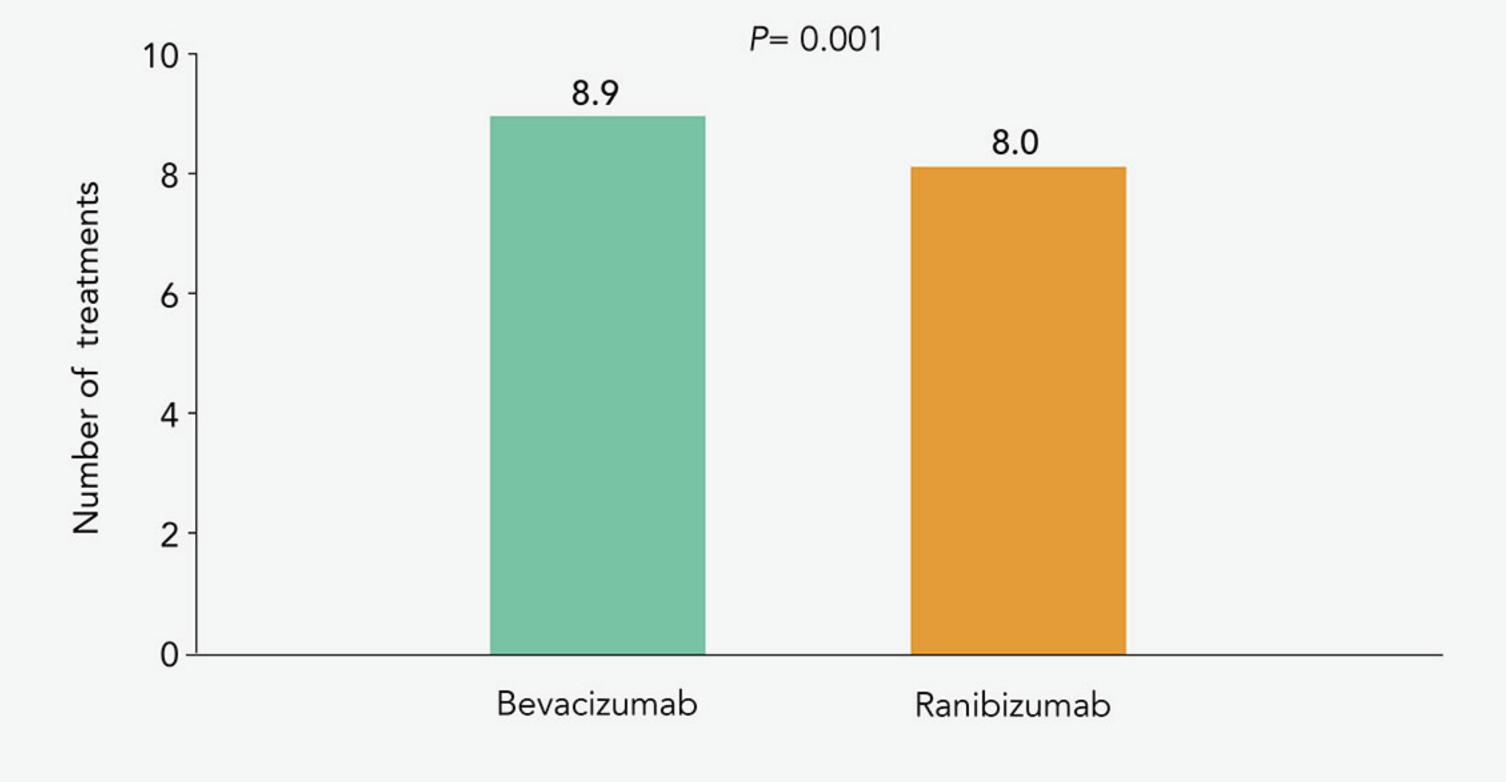

Mean central retinal thickness (CRT) was significantly reduced with ranibizumab and bevacizumab. However, there was no significant difference between the 2 treatment groups at 1 year.

95% CI of mean difference, -13 to 28; *P*= 0.460

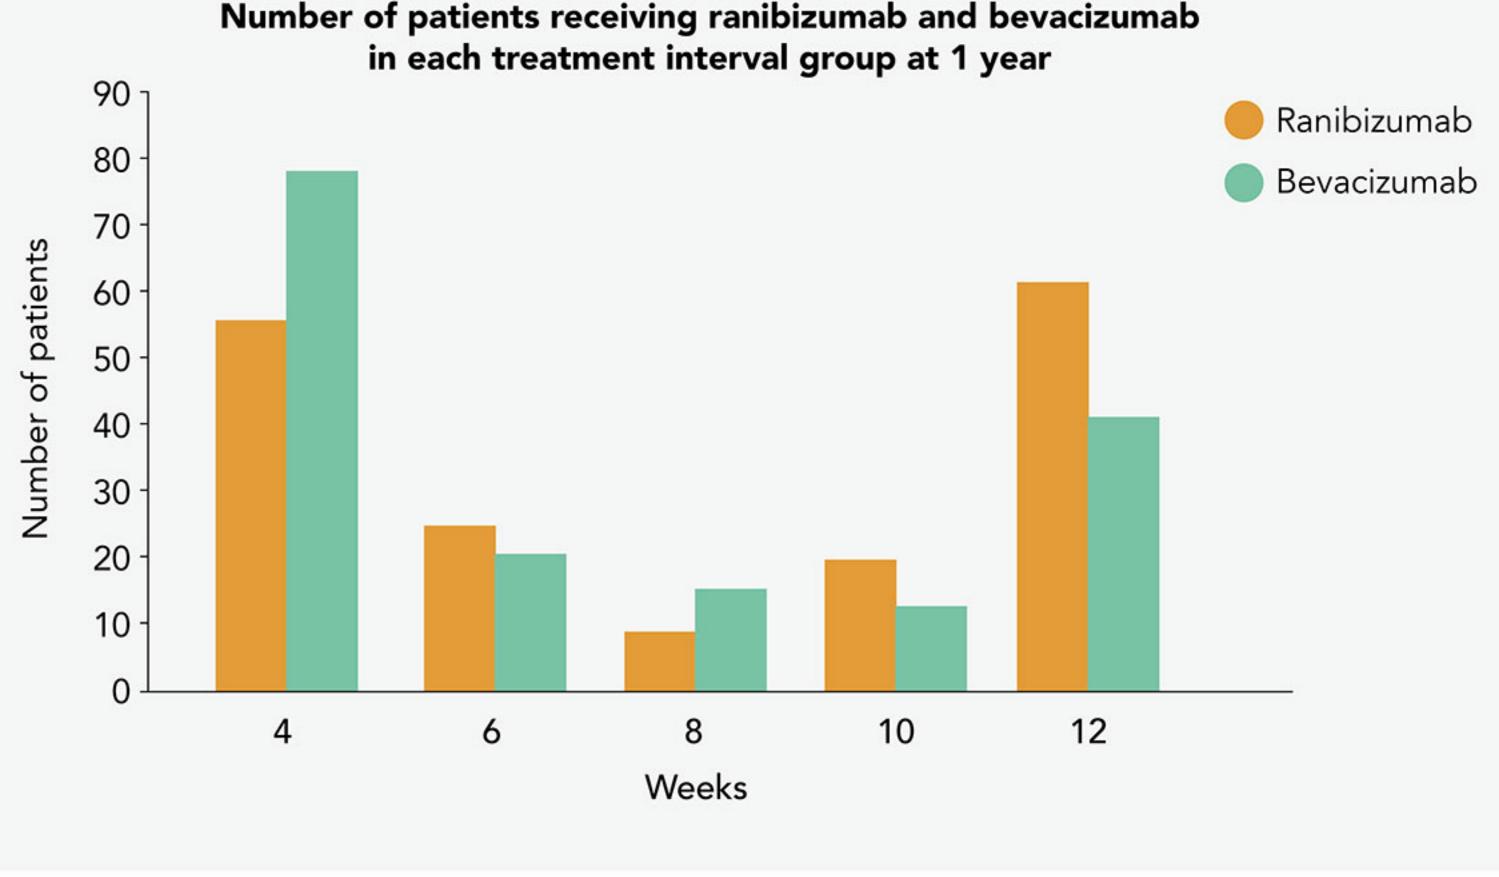

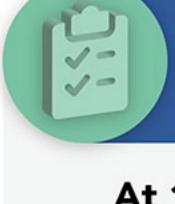

There was a statistically significant difference in number of treatments needed

At 1 year, there were more patients receiving injections every 4 weeks in the bevacizumab group and more patients receiving injections with a 12-week interval in the ranibizumab group

Conclusions

At 1 year, there was a significantly larger portion of patients receiving ranibizumab compared with bevacizumab who demonstrated complete resolution of fluid. There was a slightly larger CRT in the bevacizumab group compared with the ranibizumab group, but this was not statistically significant.

ranibizumab group, but this was not statistically significant.

Bevacizumab and ranibizumab had equivalent effects on visual acuity at 1 year when administered according to a treat-and-extend protocol. The visual acuity results at 1 year

were comparable to those of other clinical trials with monthly treatment. The numbers of

serious adverse events were small.
